

Enriching and Validating Data

Validation

Validations

- **Check** attribute values to **reject** invalid records
- Can be used during **Pre-consolidation** and **Post-consolidation**
- 3 types:
 - **SemQL** language
 - **Java Plug-in**
 - **Model Driven:**
 - Mandatory attributes
 - LOVs
 - Unique Keys
 - References

Name

John_Doe

Special characters are not allowed

Customer Name

M

Customer Name length must be longer than one character!

Validations

Validation conditions return a Boolean value: **true** or **false**

```
LENGTH(CustomerName) > 1
```

The screenshot shows the configuration for a validation rule named 'CheckCustomerNameLength'. The interface includes a breadcrumb trail: 'CustomerTrainingDemo' > 'Customer' > 'CheckCustomerNameLength'. A 'Details' tab is selected. Under the 'Name and Description' section, the following fields are visible:

- Auto Fill:** ☒
- Name:** CheckCustomerNameLength
- Label:** Check Customer Name Length
- Description:** (empty)
- Condition:** LENGTH(CustomerName) > 1 (This field is highlighted with a red rectangle)
- Error Message:** Customer Name must be longer than one character!
- Validation Scope:** Pre-consolidation only

Pre vs Post Consolidation Validation

Pre-Consolidation Validation

- Applied to data from all publishers to this entity, **after enrichment**

Post-Consolidation Validation

- Applied on **de-duplicated** and **consolidated** data only

Pre-consolidation validations remove erroneous source records from the certification process, and their data does not contribute to the golden records. Post-consolidation validations only flag erroneous golden records. They still appear as Golden Records with Errors.

Which Validation do you need to use?

An *IsValidGeocodedAddress* validation checks that *GeocodedAddress* is not empty and *GeocodedAddress.Quality* is high enough

- The matching process for Customer uses the *GeocodedAddress* to match customers from all sources
- Enrichers will create a *GeocodedAddress*, if possible
- If the resulting *GeocodedAddress* is empty or not good enough, then these customer should not be processed further

Pre-consolidation

A *CheckNullRevenue* validation checks that ***Revenue* is not null** for a *Customer* entity.

- *Customer* data is published from the CRM and Sales applications.
- Only the Sales publisher loads revenue data. CRM leaves it null
- Consolidation needs critical info from the CRM application (email, name, address, etc...)

Post-consolidation
